TITLE: Spectral theory of the operator which is the sum of the Laplace operator and a bounded Hermitian operator, in an unbounded space

SOURCE: Izv. Matem. Anal., no. 3, 1963, 122-134

TOPIC TAGS: Laplace operator, Hermitian operator, spectral analysis resolvent

ABSTRACT: The author investigates spectral analysis of the operator  $\Delta u + \mu u$ , where  $\Delta u$  is a Laplace operator, in unbounded three-dimensional space.  $K$  is a bounded Hermitian operator. Lower case Latin letters denote vectors of three-dimensional space with origin at the center of the coordinates and also denote the points which are the ends of these vectors;  $dp$  is an element of volume;  $d\tilde{p}$  is an element of the surface; and  $E$  is the whole space. If  $D$  is a subregion of  $E$ , then  $L^2_{\text{sup}}(D)$  denotes the usual Hilbert space of square integrable functions with domain  $D$ . The theorems are given in the Enclosures. "The author takes the opportunity to express his deep gratitude to Professor A. Ya. Povzar for the statement of the problem and his aid in writing this article." Orig. art. has: 58 formulas.

TITLE: Aerial reconnaissance supporting an amphibious operation

SOURCE: Morskoy sbornik, no. 8, 1965, 25-31

TOPIC TAGS: aerial photograph, aerial reconnaissance, amphibian operation, photographic reconnaissance, radar reconnaissance

ABSTRACT: Amphibious operations were studied on the basis of U.S. experiences in World War II. The general reconnaissance requirements for each operation are the same, requiring close coordination of the various air arms of all the services. Prior to the development of operational plans, the terrain must be surveyed, defensive installations detected, enemy disposition noted, supply and reserve potentials studied, etc. During transit of the landing force to the debarkation area, convoys must be protected, and enemy forces capable of interrupting the operation must be kept under surveillance. During the landing, aerial reconnaissance reports assist in controlling gunfire, organizing landing operations, and noting changes in the enemy's strength. To ensure that the necessary information is gathered and rapidly relayed to the commanders, an aerial

Card 1/2

L 1331-66  
ACCESSION NR: AP5020411

reconnaissance force should be assembled, and a communication network established. Visual reconnaissance, chiefly used during the combat stage, provides speed and flexibility, but is limited by meteorological conditions and delivers only subjective reports, not documented material for later study. Aerial photography is useful during the planning stages. It permits detailed study, but the time delay in processing the photographs is a disadvantage during combat. Radar reconnaissance is useful during poor visibility operations, provides long range visibility, and is essential for detection of the enemy's electronic potential. Infrared reconnaissance has many advantages, its chief drawback being that its operation requires highly qualified specialists.

SOURCE: Ref. zh. Khimiya. Abs. 88550

AUTHOR: Zalukayev, L. P.; Pivnav, V. I.

TITLE: Evaluation of the effectiveness of a series of antioxidants for rubbers by the NMR method

CITED SOURCE: Tr. Labor. khimii vysokomolekul. soyedineniy. Voronezhsk. un-t., vyp. 2, 1963, 140-141

TOPIC TAGS: synthetic rubber, rubber antioxidant, nuclear magnetic resonance, rubber film oxidation

TRANSLATION: Eight antioxidants were tested in SKB (synthetic butadiene rubber) films: (a) four aromatic amines and (b) four phenols. The content of anti-oxidants was 0.5%. The films were oxidized in air at 130C. In the course of the oxidation, the ratio of the amplitudes of the first derived NMR signals of the unoxidized ( $A_0$ ) and oxidized (A) rubbers was measured. All the antioxidants of group (a) stopped the autocatalysis at the very start of the oxidation,  $A_0/A$

Card 1/2

L 55863-65

ACCESSION NR: AR5014995

being constant. The antioxidants of group (b) retarded only the process of cross-linking at the start of the oxidation; their induction period began some time after the oxidation had begun. The antioxidants studied were arranged in the following order of decreasing effectiveness: (a) N,N'-dinaphthyl-p-phenylenediamine, N,N'-di- $\beta$ -naphthyl-p,p'-diaminodiphenylmethane; (b) 2,6-di-tert-butyl-4-methylphenol, di-o-cresol monosulfide, 2,5-di-tert-amylhydroquinone, N-sec-octyl-p-anisidine. TITLE: A study of thermal aging in protector rubbers made from natural rubber by  
nuclear magnetic resonance

SOURCE: Kauchuk i rezina, no. 3, 1964, 19-21

TOPIC TAGS: thermal aging, rubber, nuclear magnetic resonance, magnetic field,  
aging coefficient, oxidation kinetics

ABSTRACT: The nuclear magnetic resonance (NMR) method is briefly described. The  
phenomenon involves magnetic moments acquired by the nuclei of element atoms  
placed in a constant magnetic field of magnitude  $H_0$ . For a proton-nucleus atom of  
hydrogen, the orientation energy is determined from

$$\Delta E = 2\mu H_0$$

Card 1/2

ACCESSION NR: AP4026365

and the frequency from

$$h\nu_0 = 2\mu H_0 .$$

This method has been used to determine the thermal aging of 2-mm thick protector rubber specimens with various antioxidants at 100, 120, and 140°C temperatures in atmospheric air. The amplitude change  $\Delta A$  of an arbitrary NMR signal is represented graphically as a function of time and temperature. At 120 and 140°C temperatures a plateau is observed in the curves for aging times of 90 and 30 hours respectively. A table is presented of aging coefficients, comparing the oxidation kinetics of eleven specimens by the NMR method and a mechanical method. The NMR method is shown to be a useful means for investigating thermal aging in rubber. Orig. art. has: 3 formulas, 2 tables, and 1 figure.

TITLE: The application of nuclear magnetic resonance to the study of aging of rubber

SOURCE: Vy\*sokomolekulyarny\*ye soyedineniya, v. 6, no. 3, 1964, 538-540.

TOPIC TAGS: rubber, rubber aging, rubber oxidation, structuration, oxidation inhibitor, neozone D, ionol, dinaphthylphenylenediamine, nuclear magnetic resonance, induction period, autocatalytic process

ABSTRACT: Films of butadiene rubber SKB(0.3 mm thick), containing 0.25 or 0.5% of various antioxidants, were subjected to oxidation at 130C in air for various periods up to 600 hours. The amplitude of the signal derivative of proton nuclear magnetic resonance (NMR) of these samples was recorded, and the results were compared with data from the volumetric studies. As is shown on the chart (Fig. 1 of the Enclosure), the oxidation induction period for rubber containing 0.5% neozone D is approximately twice that of the sample containing 0.25% of this antioxidant. A steep climb of the curve following the induction period is typical for

Card

1/4

ACCESSION NR: AP4030373

neozone D. When measured by the NMR technique, the oxidation induction period of sample containing 0.25% neozone D was 22 hours, as against 100 hours needed in the volumetric method. This is explained by the fact that after 22 hours the oxidation process acquires an autocatalytic aspect. The use of N,N'-dinaphtyl-p-phenylenediamine (DNPd) as antioxidant produced an NMR curve of similar character, but here the induction period was extended to 550 hours and was not affected by the amount of antioxidant. The antioxidant ionol produced NMR curves of a staggered character, in which segments pertaining to autocatalytic oxidation are followed by periods of stabilization. The authors have advanced a theory that here the inhibition is due to the formation of oxidation products of ionol (such as diphenols and diquinones). Orig. art. has: 1 chart and 4 formulas.

TITLE: Nature and energy spectrum of solar-diurnal and semidiurnal variations at the time of some Forbush effects

SOURCE: Geomagnetizm i aeronomiya, v. 5, no. 4, 1965, 760-762

TOPIC TAGS: diurnal variation, solar spectrum, cosmic ray intensity, geomagnetic field

ABSTRACT: This paper discusses solar-diurnal and semidiurnal variations on 1-2 November, 11-13 April 1960 and 29-30 April and 1 May 1962. The study was based on data from the world network of stations recording the neutron component of cosmic ray intensity, corrected for the barometric effect. The harmonic analysis was based on data corrected for the Forbush effect. The plotted data show that there is a clearly expressed diurnal variation of both cosmic rays and the geomagnetic field. Cosmic ray data have a well-expressed inverse correlation with the H component in the first two cases considered, when there were moderate magnetic storms; in the third case there was a direct correlation, when the geomagnetic field was restored after the Forbush effect. Analysis of the

Dependence of the time of the maximum of the diurnal and semidiurnal variations on the cutoff energy revealed that the time of the maximum of the diurnal variation is displaced gradually to the early hours with an increase of cutoff energy. Nothing definite can be said concerning the phase of the semidiurnal variation. It is shown that the first two cases can be attributed to a close source and the third case can be attributed to a distant source. In these cases the energy spectra are somewhat different. In the case of a near source the spectrum is somewhat harder than for the case of a distant source. Orig. art. has: 2 figures and 1 table. [JPRS]

TITLE: Investigation of cosmic ray intensity decreases of the Forbush type as a function of solar activity

SOURCE: Cosmagnetism i aeronomiya, v. 5, no. 5, 1965, 826-830

TOPIC TAGS: solar activity, cosmic ray intensity

ABSTRACT: A study has been made of a number of characteristic Forbush decreases occurring in 1957-1962. The authors have computed the energy spectra at the time of the decreases and at the time of recovery. It is demonstrated that at the time of one Forbush decrease the spectrum can change rather sharply. No definite pattern was discovered in the change of the energy spectra of Forbush decreases with a change of solar activity. The rate of change of cosmic ray intensity at the times of the decrease and recovery is dependent on the direction of arrival of the particles. Orig. art. has: 3 figures. [JPRS]

SOURCE: AN SSSR. Investiya. Seriya fizicheskaya, v. 29, no. 10, 1965, 1894-1897

TOPIC TAGS: Cosmic ray intensity, cosmic ray variation, magnetic storm, earth magnetic field, solar corpuscular radiation

ABSTRACT: The time variations of the horizontal component of the Earth's magnetic field and the cosmic ray intensity during 7 magnetic storms accompanied by Forbush decreases were compared and the results are discussed briefly. Curves are presented for the storms of 20 October - 3 November 1958 and 29 March - 15 April 1960. The cosmic ray and horizontal magnetic field intensities correlate rather well. At the time of minimum horizontal field intensity, however, there was a small maximum in the cosmic ray intensity; this is ascribed to a shift of the rigidity threshold. During recovery the small-amplitude variations of cosmic-ray intensity observed at high-latitude stations correlated negatively with those of the horizontal magnetic

Card 1/2

TITLE: Change in cosmic ray intensity on quiet and magnetically disturbed days

CITED SOURCE: Sb. Kosmich. luch. No. 5. M., AN SSSR, 1963, 149-153

TOPIC TAGS: cosmic ray, cosmic ray intensity, geomagnetism, stratosphere, upper atmosphere, magnetic storm, Forbush decrease

TRANSLATION: The authors compare the change in cosmic ray intensity on the basis of measurements in the stratosphere over Minneapolis, Murmansk and Moscow, on the one hand, and sea-level data at Ottawa, Churchill and Herstonceaux on the other. The ratio of the amplitudes of variations for Minneapolis, Murmansk and Moscow varies from 35, 29 and 2, respectively on quiet days to 22, 12 and 4, respectively at the time of magnetic storms. It is shown that: 1) on magnetically quiet days the relative increase of low-energy cosmic ray intensity (up to 0.3 Bev) in the stratosphere exceeds by many times the latitude effect with a cutoff rigidity of ~ 2 Bev; 2) on magnetically disturbed days there is an opposite phenomenon -- in the high latitudes the relative amplitude of the Forbush

Card 1/2

L 32004-65

ACCESSION NR: AR4045185

decrease decreases, but at the lower latitudes (with the cutoff rigidity  $\sim 3$  Bev) it increases almost by a factor of 2. Bibliography with 10 items. L. Dorman.

**TITLE:** Variations in intensity and anisotropy of cosmic rays during world magnetic storms and auroras at low latitudes

**SOURCE:** Ref. zh. Astronomiya, Otdel'ny'y vy'p., Abs. 8.81.381

**CITED SOURCE:** Sb. Kosmich. luchl. No. 5, M., AN SSSR, 1963, 5-81

**TOPIC TAGS:** cosmic ray, magnetic storm, geomagnetism, upper atmosphere, aurora, magnetic field, corpuscular stream, Forbush decrease

**TRANSLATION:** Data from the world network of cosmic ray stations during the period of high solar activity 1957-1959 have been used in a study of the following problems. 1. During the entire IGY-IGC period the network of hydrometeorological stations of the Kazakh SSR observed 15 auroras, 3 of which were associated with moderate magnetic storms, 4 with large storms and 9 with very large magnetic storms. Observational data on the hard and neutron component of cosmic rays are used in an investigation of the Forbush decreases during these storms. Changes in cosmic ray intensity are compared with changes in the H component of the geomagnetic field and the K index of magnetic

Card 1/4

15713-65  
ACCESSION NR: AR4049320

activity. An evaluation is made of the character of change in the energy spectrum of the Forbush decrease with time in periods of decrease and restoration of intensity (from the ratio of the amplitudes of the effects in the neutron and hard components). It is shown that in most cases with increasing restoration of intensity there will be an appreciable softening of the spectrum, which agrees with the model attributing the Forbush decreases to the effect of magnetic fields of corpuscular streams on cosmic rays. 2. A similar analysis was made for Forbush decreases caused by magnetic storms which were not accompanied by auroras in the Kazakh SSR. According to observational data on cosmic rays, the corpuscular streams causing these storms in all probability had a lower density of kinetic energy and at the time of the interaction with the geomagnetic field formed a cavity of greater size than did the corpuscular streams in the first case (when auroras were observed). With respect to the magnetic properties, no appreciable difference was noted between the corpuscular streams causing and not causing auroras in the middle and low latitudes. 3. Using the results of determination of the rigidity of the geomagnetic cutoff for the world network of stations, taking into account six harmonics of the field on the basis of data from ground observations of the hard and neutron components and the results of stratospheric and underground observations of cosmic rays, the authors

Card 2/4

L 15713-65  
ACCESSION NR: AB4049320

have found the energy spectrum of Forbush decreases for 18 magnetic storms on the basis of the coupling coefficients method. It is shown that the primary variation  $\delta D(E)/D(E)$  in the region of energies  $E$  up to 15 Bev changes appreciably from case to case in the range 0.05-0.25 with a tendency to an increase with transition to small energies. This shows that the leakage of particles through the magnetic fields of corpuscular streams (as a result of the presence of field nonuniformities and the scattering of cosmic particles on them) decreases appreciably with a decrease in the energy of primary cosmic rays. 4. An analysis was made of the character of the change in the diurnal and semi-diurnal variations of the cosmic ray neutron component during 15 magnetic storms during the period June 1957-December 1959 (there were 9 with sudden commencements and 6 with a gradual commencement; very large 5, large 3, moderate 5 and small 2). Neutron monitor data were averaged for five latitude zones with different cutoff rigidities. Amplitude and phase of the first and second harmonics were computed for three periods: before onset of the Forbush decrease (3-hour averaging), at the time of the Forbush decrease and in the period of restoration. It is shown that fluctuations in the tendencies of change in the anisotropy of cosmic rays at the time of magnetic storms are extremely great: there are shifts in the time of the maximum to both the morning and the evening hours and there are cases of both an increase and decrease in amplitude. The results can apparently be explained on the basis of the representation of two sources of cosmic ray

Card 3/4

L 15713-65

TITLE: Anomalous large diurnal and semidiurnal cosmic ray intensity variations of 22 October - 2 November 1959

CITED SOURCE: *Sb. Kosmich. luch. No. 5. M., AN SSSR, 1963, 126-138*

TOPIC TAGS: cosmic ray, cosmic ray intensity, cosmic ray variation, solar plasma, solar cosmic ray, galactic cosmic ray, geomagnetic field, cosmic ray diurnal variation, magnetic storm

TRANSLATION: Observational data from 23 stations of the world network of cosmic ray stations have been used to investigate the anomalously large diurnal and semidiurnal cosmic ray intensity variations during the period 22 October - 2 November 1959. The entire observation period was broken down into 5 intervals: 1--quiet days, averaged for 21-22 October; 2, 3, 4--disturbed days separately for 27, 28 and 29 October, respectively; 5--averaged data for the quiet days: 1 and 2 November 1959. Data for 30 and 31 October were

Card 1/2

L 17130-65

ACCESSION NR: AR4045184

not used in the analysis because on those days there was a sharp world intensity decrease associated with a large magnetic storm with a sudden commencement. The authors determined the latitudinal and longitudinal distribution of the amplitude and phase of the first and second harmonics of the diurnal variation and also the energy spectrum of the particles responsible for the discussed effects. It is concluded that the cause of the observed diurnal variations cannot be a local source associated with changes in the geomagnetic field. It is more probable that the sought-for cause is the anisotropic modulation of galactic cosmic rays by streams of solar magnetized plasma which engulfed the earth during the period 27-29 October, although only the diffuse part of the plasma streams with a low density of kinetic energy was involved. Bibliography with 6 items. L. Dorman.

TITLE: Increase in the intensity of cosmic rays during the minimum of the Forbush effect

SOURCE: AN SSSR. Mezhdovedomst. geofizich. komitet. 7 razdel program. MGG: Kosmicheskiye luchy. Sb. statey, no. 5, 1963, 103-115

TOPIC TAGS: cosmic rays, cosmic ray intensity, Forbush effect, Forbush effect minimum, magnetic storm, magnetic storm principal phase, frozen in magnetic field, corpuscular stream, high latitude particle flux, particle hardness threshold

ABSTRACT: An analysis is made of the events occurring on 21--25 October 1958, when the intensity of the cosmic rays increased strongly at the minimum of the Forbush effect, which coincided in time with the principal phase of a magnetic storm. An analysis of the experi-

Card 1/1

ACCESSION NR: AT3012808

mental and theoretical data has shown that on 23 October 1958 the increase in intensity of the neutron component had a local character. A correlation exists with the horizontal component of the magnetic field of the earth at high latitudes, but the field cannot exert an appreciable influence on high-energy cosmic particles. It is suggested that the increase in cosmic rays at the minimum of the Forbush effect during the time of the principal phase of the magnetic storm, when the maximum decrease in the horizontal component of the magnetic field of the earth is observed, can be due to three factors which may act either separately or in conjunction: (a) inhomogeneity of the magnetic fields frozen in the corpuscular streams, (b) additional particle flux at high latitudes, transported in the traps of the magnetic fields frozen in the corpuscular streams, and (c) variation of the hardness threshold with decreasing magnetic field of the earth. TITLE: Variations of the intensity and anisotropy of cosmic rays during world-wide magnetic storms and auroras at low latitudes

SOURCE: AN SSSR. Mezhdovedomst. geofizich. komitet. 7 razdel program. MGG: Kosmicheskiye luchy. Sb. statey, no. 5, 1963, 5-61

TOPIC TAGS: cosmic rays, cosmic ray intensity, cosmic ray anisotropy, Forbush effect, corpuscular streams, low latitude aurora, primary particle energy, Forbush effect spectrum, diurnal cosmic ray variation, magnetic storm

ABSTRACT: The various effects of magnetic storms and cosmic rays for 1957--1959 are investigated using data of the world network of neutron monitor stations. These include the spectra of the Forbush

Card 1/3

ACCESSION NR: AT3012806

effect, the properties of the corpuscular streams which cause magnetic storms, the diurnal and semidiurnal variations and low-latitude auroras (in Kazakhstan). It is found that for primary particle energies  $\sim 15$  BeV the Forbush-effect spectra can be represented by constants ranging from 0.08 to 0.2. In some cases the amplitudes of the diurnal and semidiurnal variations of the cosmic rays can increase or decrease during magnetic storms, and the phase may shift towards either the morning or evening hours. For the majority of cases, however, there is a tendency for the amplitude to increase during magnetic storms and for the maximum time to shift to the morning. Auroras are observed at low latitudes mainly during the minimum of the Forbush effect at the instant when the magnetic field is minimal. The low-latitude auroras are connected with the corpuscular streams that approach the earth most closely. The various experimental data are interpreted. Although the phenomena considered are very complicated and the variation of the cosmic-ray anisotropy exhibits peculiarities in each specific case the observed data do

Card 2/4

ACCESSION NR: AT3012806

display a common feature, namely a general tendency for the time of the diurnal-variation first-harmonic maximum of the shift towards the evening hours on going from low to high geomagnetic latitudes. The strongest dependence of the first harmonic maximum time on the geomagnetic latitude is observed in this case before the magnetic storm and after the intensity of the cosmic rays has resumed its normal level. The latitude dependence weakens greatly during the time directly following the principal phase of the magnetic storm. The results are interpreted in light of the hypothesis that there are two sources of anisotropy during magnetic storms, one acting on the cosmic-ray particle trajectories outside the sphere of the influence of the geomagnetic field, and the other a nearby source associated with the asymmetrical variation of the geomagnetic field as the latter interacts with the plasma of the corpuscular streams. **Technological and design...**

motion is transmitted to the intermediate shaft on which there is a shearing torsional-moment safeguard of the press. The intermediate shaft is connected by means of a gear drive with the eccentric shaft of the press. In the slide bar there is a overload safeguard responding to a 25% overload. The press has an electropneumatic control. The press is furnished with a pump for cooling the tool and with guide blocks controlling its own operation as well as that of devices automating the charging of blanks. The press has a cast built-up frame connected with stretching bolts. The press can operated on single and automatic strokes. The device for charging blanks and removing parts from the press can have an independent drive or be driven by the moving elements of the press. Examples of parts extruded on the press are given: a socket of 75mm external diameter, a ball end with a 62mm ball and various piston pins. There are 10 figures.

TITLE: The effect of the composition of granular and dispersed components of chromite-magnesite and periclase-spinel products on their properties and behavior with respect to interaction with iron oxides

SOURCE: Ogneupory, no. 1, 1966, 44-52

TOPIC TAGS: refractory, refractory compound, refractory oxide, refractory product, chromium oxide, iron oxide, magnesite, magnesium oxide, chemical composition

ABSTRACT: The effect of composition on the properties of granular and dispersed chromite-magnesite and periclase-spinel refractories was studied. The interaction of the refractories with oxides of iron was also determined. The effect of iron oxide on the stability of the refractories was determined by the method of M. I. Diyesperova and V. A. Bron (Trudy Vostochnogo instituta ogneporov, vyp. 5, 1964), and the microstructure of the refractories was studied. The experimental results are tabulated, and photographs of the microstructure of specimens are presented. It was found that the composition of the granular and dispersed components has a great influence on the properties of the refractories. Magnesite-chromite refractories formed by introduction of part of the chromite component in the dispersed form show a greater stability towards iron oxide than specimens derived from granular chromite. The periclase-spinel

refractories, as compared with the magnesite-chromite refractories, exhibit (for the same degree of dispersion) a higher deformation temperature, lower porosity, lower gas permeability and a considerably higher stability towards the loosening effect of iron oxide. G. S. Krotova participated in the experiments. Orig. art. has: 5 tables and 6 figures.
